Minmax:

Based on this activity, I learned how the Minimax algorithm helps the AI make the best move in Tic-Tac-Toe by checking all possible outcomes and assuming the player will also play perfectly. It chooses the move that leads to the best possible result (win or draw). However, since Minimax can be slow, we used Alpha-Beta pruning to make it faster by skipping unnecessary moves that don't affect the final decision. Both methods give the same results, but Alpha-Beta pruning makes the AI more efficient and quicker in choosing its moves.

Reflection:

The problems I've encountered in this activity were that there was a random alphabeta/minimax call outside the game loop that caused errors. It was also slower because it used the plain minimax algorithm. I fixed these issues by using alphabeta() for the AI, removing the stray code, adding a safety check for missing moves, and improving the input validation.
